CHAPTER 5

PRIORITY QUEUES (HEAPS)

—— delete the element with the highest \ lowest priority

§ 1 ADT Model

Objects: A finite ordered list with zero or more elements.

Operations:

- PriorityQueue Initialize(int MaxElements);
- void Insert(ElementType X, PriorityQueue H);
- ElementType DeleteMin(PriorityQueue H);
- ElementType FindMin(PriorityQueue H);

§ 2 Simple Implementations

- **Array :**
  - **Insertion** — add one item at the end ~ $\Theta(1)$
  - **Deletion** — find the largest \ smallest key ~ $\Theta(n)$
    remove the item and shift array ~ $O(n)$
- **Linked List :**
  - **Insertion** — add to the front of the chain ~ $\Theta(1)$
  - **Deletion** — find the largest \ smallest key ~ $\Theta(n)$
    remove the item ~ $\Theta(1)$
- **Ordered Array**
  - **Insertion** — ~ $O(n)$

Better since there are never
more deletions than insertions

- **Ordered L**
  - **Insertion** — find the proper position ~ $O(n)$
    add the item ~ $\Theta(1)$
  - **Deletion** — remove the first \ last item ~ $\Theta(1)$

Binary Search Tree :

Now you begin to know me ☺

better option?

always dangerous.

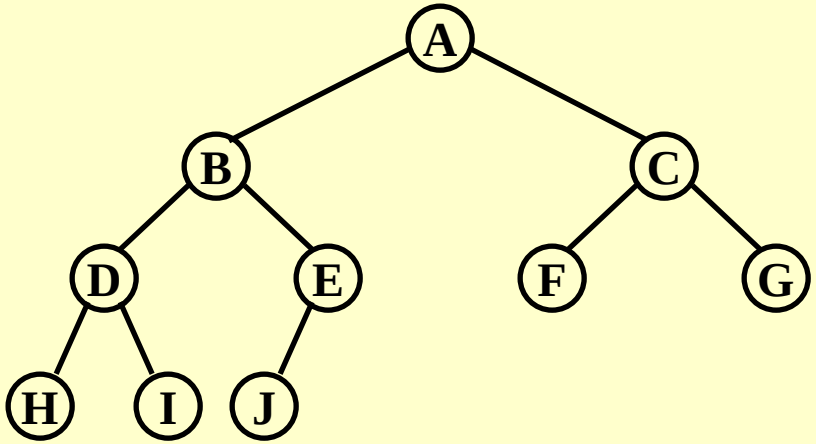
§ 3 Binary Heap

1. Structure Property:

【Definition】A binary tree with n nodes and height h is complete iff its nodes correspond to the nodes numbered from 1 to n in the perfect binary tree of height h.

A complete binary tree of height h has between 2^h and $2^{h+1} - 1$ nodes. ⇒ $h = \lfloor \log N \rfloor$

❖ Array Representation : BT [n + 1] (BT [0] is not used)



BT

0	1	2	3	4	5	6
	A	B	C	D	E	F

7	8	9	10	11	12	13
G	H	I	J			

【Lemma】If a complete binary tree with n nodes is represented sequentially, then for any node with index i, $1 \le i \le n$, we have:

(1) index of $parent(i) = \begin{cases} \lfloor i/2 \rfloor & \text{if } i \neq 1 \\ \text{None} & \text{if } i = 1 \end{cases}$

(2) index of $left\_child(i) = \begin{cases} 2i & \text{if } 2i \le n \\ \text{None} & \text{if } 2i > n \end{cases}$

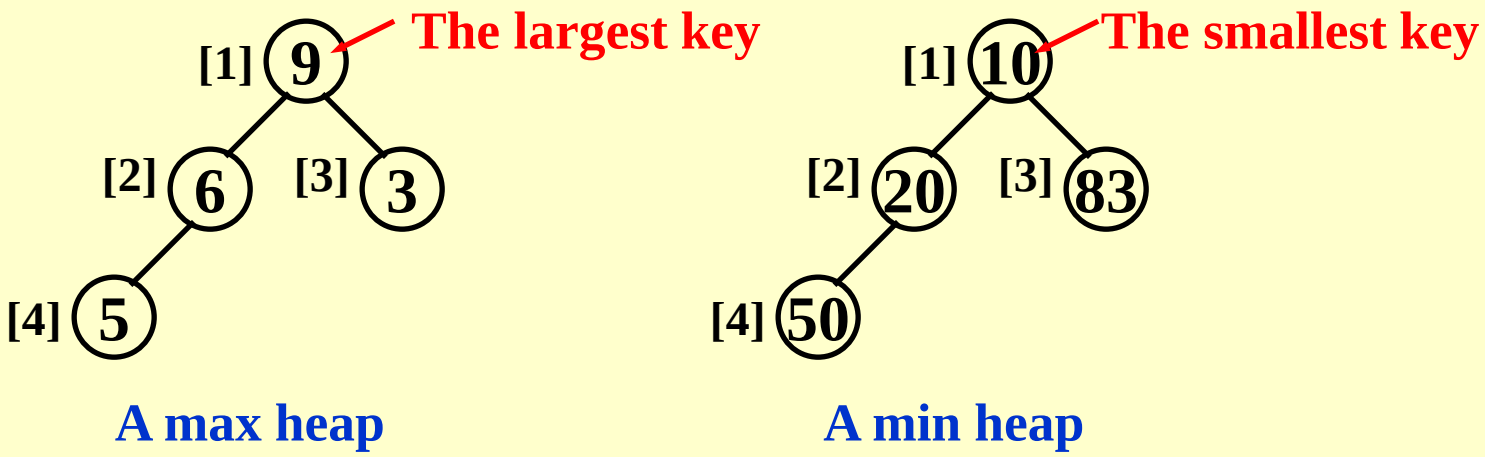
(3) index of $right\_child(i) = \begin{cases} 2i+1 & \text{if } 2i+1 \le n \\ \text{None} & \text{if } 2i+1 > n \end{cases}$

```
PriorityQueue  Initialize( int  MaxElements )
{
    PriorityQueue  H;
    if ( MaxElements < MinPQSize )
            return  Error( "Priority queue size is too small" );
    H = malloc( sizeof ( struct HeapStruct ) );
    if ( H ==NULL )
            return  FatalError( "Out of space!!!" );
    /* Allocate the array plus one extra for sentinel */
    H->Elements = malloc(( MaxElements + 1 ) * sizeof( ElementType ));
    if ( H->Elements == NULL )
            return  FatalError( "Out of space!!!" );
    H->Capacity = MaxElements;
    H->Size = 0;
    H->Elements[ 0 ] = MinData;  /* set the sentinel */
    return  H;
}
```

2. Heap Order Property:

【Definition】A **min tree** is a tree in which the key value in each node is no larger than the key values in its children (if any). A **min heap** is a **complete** binary tree that is also a min tree.

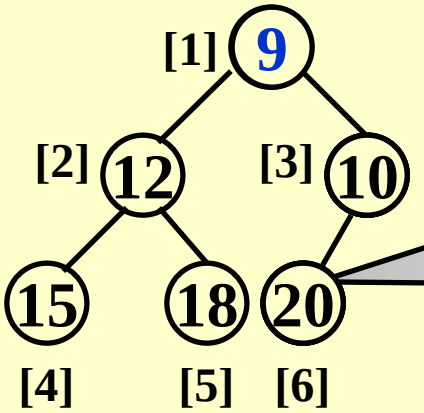
Note: Analogously, we can declare a ***max*** heap by changing the heap order property.



3. Basic Heap Operations:

☞ **insertion**

➢ **Sketch of the idea:**



The only possible position for a new node since a heap must be a complete binary tree.

Case 1 : new_item = 21 20 < 21 ✓

Case 2 : new_item = 17 20 > 17 10 < 17 ✓

Case 3 : new_item = 9 20 > 9 10 > 9 ✓

```
/* H->Element[ 0 ] is a sentinel */
void  Insert( ElementType  X,  PriorityQueue  H )
{
    int  i;

    if ( IsFull( H ) ) {
        Error( "Priority queue is ful
        return;
    }

    for ( i = ++H->Size; H->Elements[ i / 2 ] > X; i /= 2 )
        H->Elements[ i ] = H->Elements[ i / 2 ];

    H->Elements[ i ] = X;
}
```

H->Element[0] is a *sentinel* that is no larger than the minimum element in the heap.

Faster than *swap*

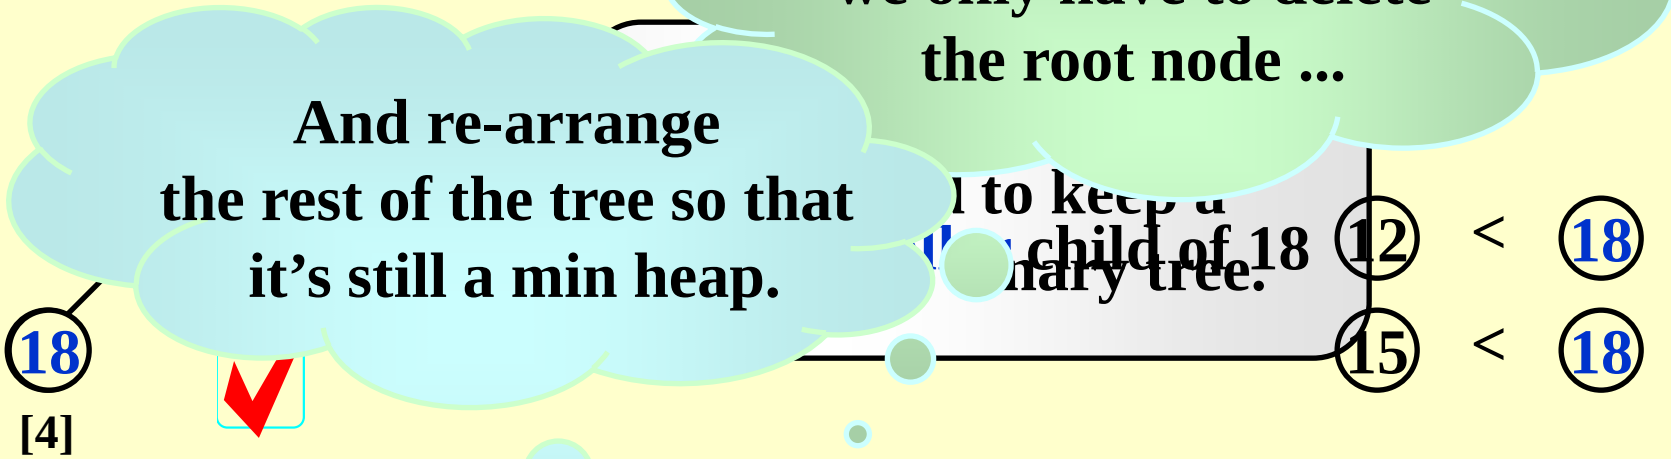
$$T(N) = O(\log N)$$

☞ DeleteMin

➢ Sketch of the idea:

Ah! That's simple -- we only have to delete the root node ...

And re-arrange the rest of the tree so that it's still a min heap.



$$T(N) = O(\log N)$$

```
ElementType  DeleteMin( PriorityQueue  H )
{
   int  i, Child;
   ElementType  MinElement, LastElement;
   if ( IsEmpty( H ) ) {
       Error( "Priority queue is empty" );
       return  H->Elements[ 0 ];   }
   MinElement = H->Elements[ 1 ];  /* the min element */
   LastElement = H->Elements[ H->Size-- ];  /* take last and reset size */
   for ( i = 1; i * 2 <= H->Size; i = Child ) {  /* Find smaller child */
       Child = i * 2;
       if (Child != H->Size && H->Elements[Child+1] < H->Elements[Child])
                 Child++;
       if ( LastElement > H->Elements[ Child ] )  /* Percolate one level */
                 H->Elements[ i ] = H->Elements[ Child ];
       else      break;   /* find the proper position */
   }
   H->Elements[ i ] = LastElement;
   return  MinElement;
}
```

Can we remove it by adding another sentinel?

4. Other Heap Operations:

Note: Finding any key except the minimum one will have to take a linear scan through the entire heap.

☞ **DecreaseKey (P, Δ, H)** *Percolate up*

sys. admin.

Lower the value of the key in the heap H at position P by a positive amount of Δ……so my programs can run with highest priority ☺.

☞ **IncreaseKey (P, Δ, H)** *Percolate down*

sys. admin.

Increases the value of the key in the heap H at position P by a positive amount of Δ……drop the priority of a process that is consuming excessive CPU time.

Delete (P, H)

DecreaseKey(P, ∞, H); DeleteMin(H)

sys. admin.

Remove the node at position P from the heap H …… delete the process that is terminated (abnormally) by a user.

BuildHeap (H)

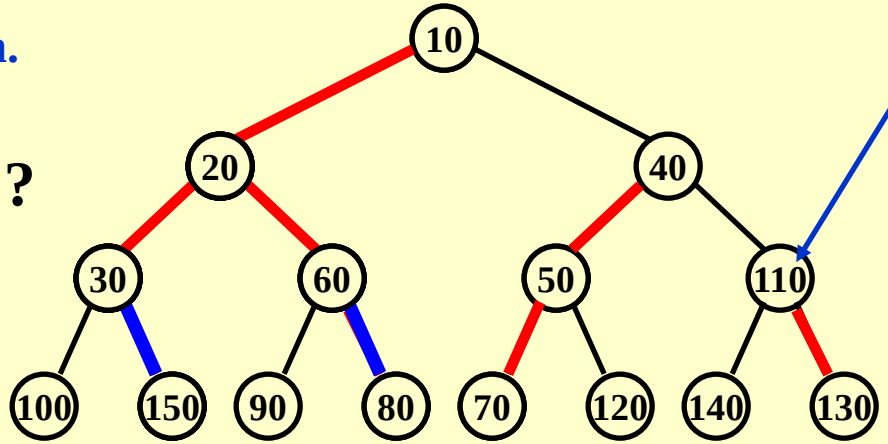
Nehhhhh that would be toooo slow !

sys. admin.

Place *N* input keys into an empty heap H.

150, 80, 40, 30, 10, 70, 110, 100, 20, 90, 60, 50, 120, 140, 130

T (*N*) = ?



PercolateDown (7)
PercolateDown (6)
PercolateDown (5)
PercolateDown (4)
PercolateDown (3)
PercolateDown (2)
PercolateDown (1)

【Theorem】For the perfect binary tree of height h containing $2^{h+1} - 1$ nodes, the sum of the heights of the nodes is $2^{h+1} - 1 - (h + 1)$.

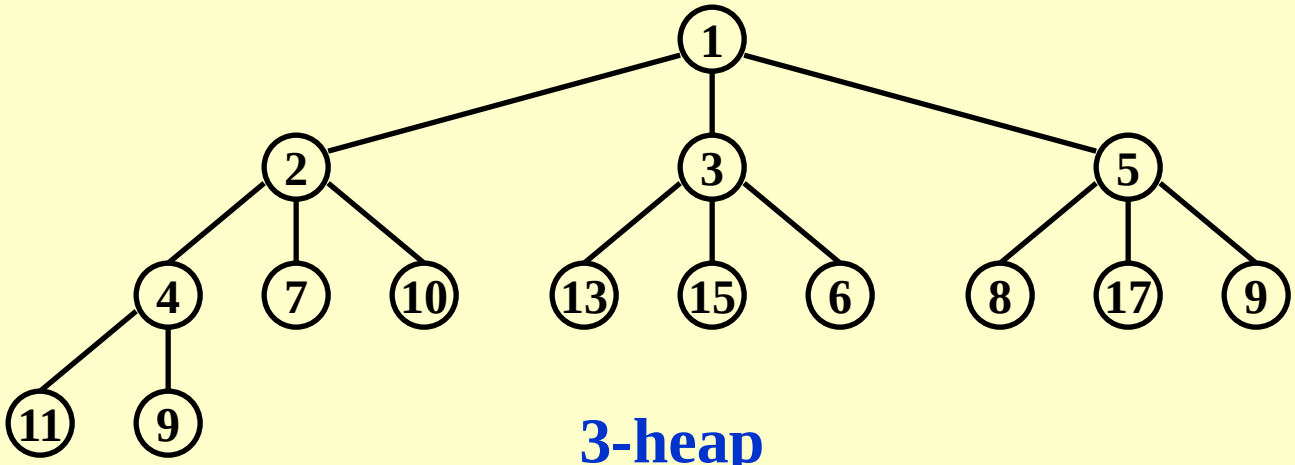
$\rightarrow T(N) = O(N)$

§ 4 Applications of Priority Queues

〖Example〗Given a list of N elements and an integer k. Find the kth largest element.

How many methods can you think of to solve this problem? What are their complexities?

§ 5 *d*-Heaps ---- All nodes have *d* children



3-heap

Question: Shall we make *d* as large as possible?

Note: ① DeleteMin will take $d - 1$ comparisons to find the smallest child. Hence the total time complexity would be $O(d \log_d N)$.
② *2 or /2 is merely a bit shift, but *d or /d is not.
③ When the priority queue is too large to fit entirely in main memory, a *d*-heap will become interesting.
